ROBOTICS WITH PLYMOUTH UNIVERSITY

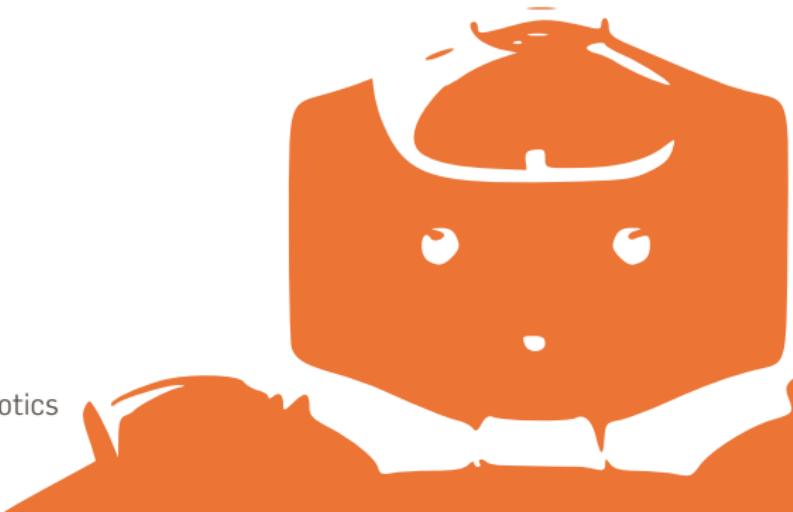

ROCO222

Intro to Sensors and Actuators

Stepper motors

Séverin Lemaignan

Centre for Neural Systems and Robotics
Plymouth University

WHAT HAVE WE DONE SO FAR?

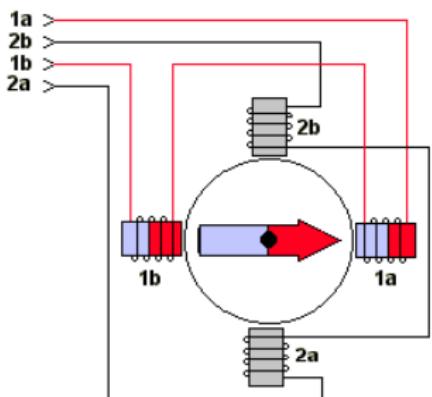

- **Week 1** – Arduino + Encoders
- **Week 2** – Electromagnetism and DC motors 1
- **Week 4** – Electromagnetism and DC motors 2
- **Week 5** – Magnets, brushless motor, motor control
- **Week 6** – Stepper motors
- **Week 7** – *no lecture*
- **Week 8** – Non-electrical actuators (Martin Stoelen)
- **Week 9** – ROS middleware, joint state, kinematics 101, visualisation
- **Week 10** – Software engineering for robotics
- **Week 11** – Induction motors
- **Week 12** – Sensors
- **Week 13** – Exam preparation

LABS

- **Week 1** – Git, Linux, command-line
- **Week 2** – DC motor design
- **Week 4** – Incremental encoder
- **Week 5** – Arduino motor control
- **Week 6** – Arduino and Stepper motors
- **Week 7 – Lab on Monday for everyone** Servo project intro
- **Week 8** – Design for 3D printing (Jake)
- **Week 9** – Servo project cont'd
- **Week 10** – Servo project cont'd
- **Week 11** – Servo project cont'd
- **Week 12** – Servo project final

STEPPER MOTORS

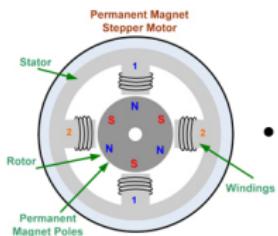

STEPPER MOTOR BASIC PRINCIPLE

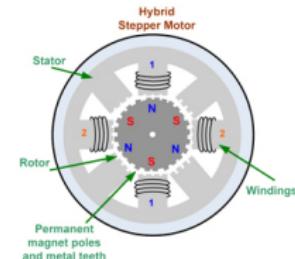

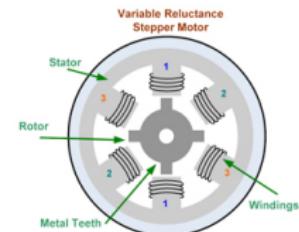

- A stepper motor is a synchronous electric motor.
 - The rotor's equilibrium position occurs when aligned with the stator's magnetic field
 - By sequencing the current in the coils, one generates a rotating magnetic field, which in turn generates a rotation of the rotor, one step at time.

SEVERAL BASIC TYPES OF STEPPING MOTORS

- There are different types of stepper motors
 - Variable reluctance stepper motors with metal teeth

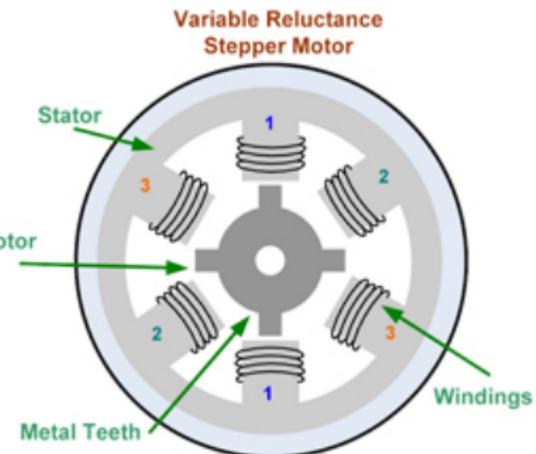

- Permanent magnet stepper motors
- Hybrid stepper motors with both permanent magnets and metal teeth
- 2 phase hybrid steppers are the main type of motor actually used in practice

VARIABLE RELUCTANCE MOTOR

- In a reluctance stepper motor the rotor consists of a toothed cylinder and it is made of ferromagnetic material
- Rotor is not permanently magnetized
- A stator consists of windings that generate a magnetic field
- The rotation of a variable reluctance stepping motor is produced by energizing individual windings

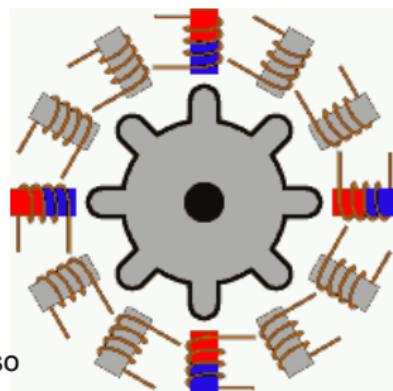

- When a winding is energized, current flows and magnetic poles are created, which attracts the nearest metal teeth of the rotor
- Thus as current it passed through the stator coils the rotor moves one step to align the offset teeth to the energized winding, thereby minimizing the reluctance of the magnetic path

VARIABLE RELUCTANCE STEPPER MOTOR OPERATION

- When the rotor is aligned and held at the current position, the next adjacent windings can be energized to continue rotation in another step.
- Alternatively the current winding can remain energized to hold the motor at its current position.
- When the phases are turned on in the appropriate sequence, the rotor rotates continuously

Reluctance stepper motors have the advantages:

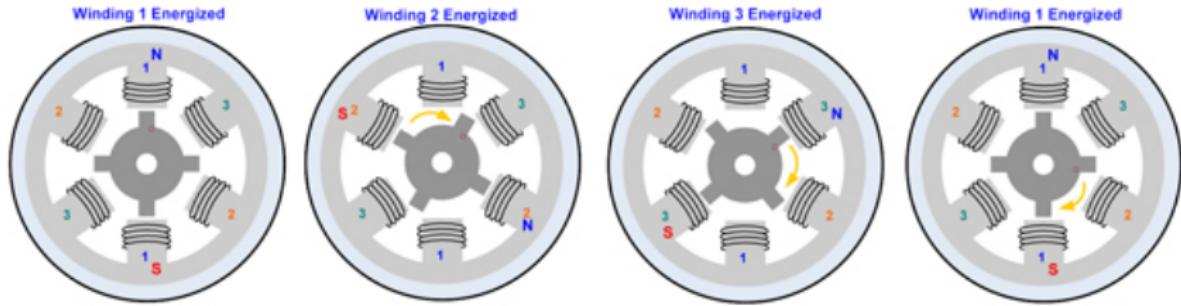

- A cheap way to generate high power densities
- Simple to manufacture
- Do not have problems of inducing EMF in the stator coils and so can easily run a high speeds.

Reluctance stepper motors have the disadvantages:

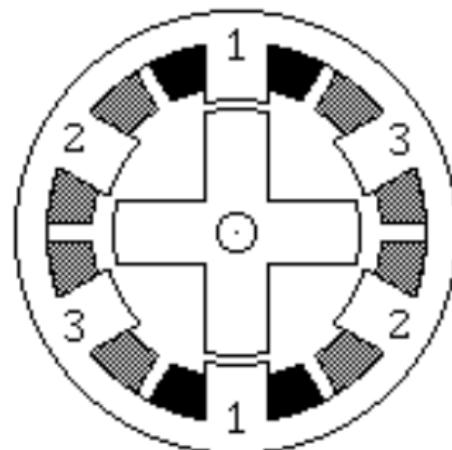

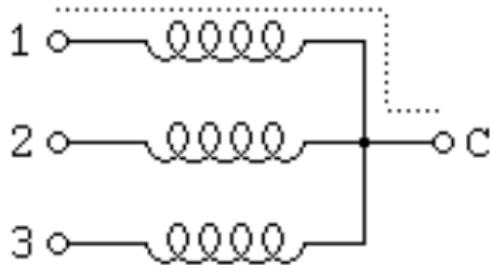

- Have limited output torque
- Have a lot of torque ripple and are noisy

VARIABLE RELUCTANCE STEPPER MOTOR: SEQUENCING

Winding 1	0	+	0	0
Winding 2	0	0	+	0
Winding 3	+	0	0	+

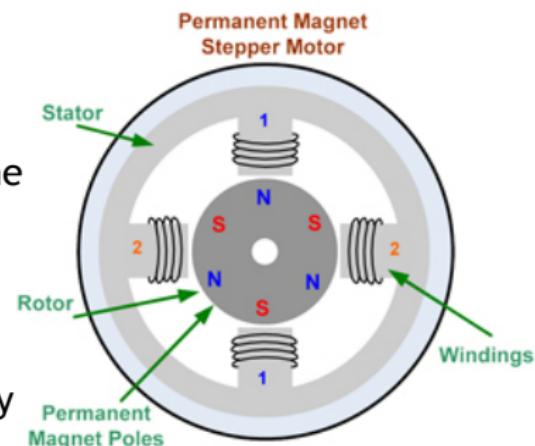

VARIABLE RELUCTANCE MOTOR COILS

Example motor with 3 field windings

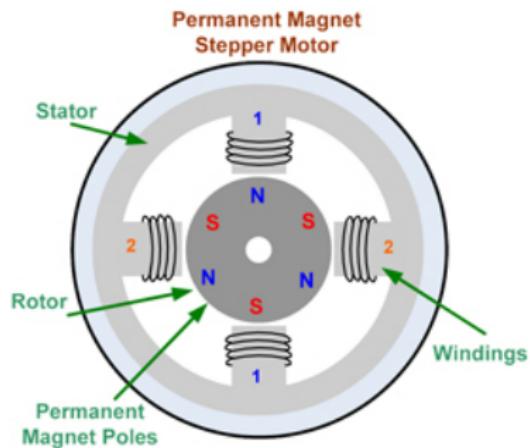

PERMANENT MAGNET STEPPER MOTOR

- A permanent magnet stepping motor consists of a stator with windings and a rotor with permanent magnet poles
- When a winding is energized, a north and south pole are created, depending on the polarity of the current flowing
- These generated poles attract the permanent poles of the rotor
- The rotor moves one step to align the offset permanent poles to the corresponding energized windings
- When the phases are switched on sequentially the rotor is continuously rotated

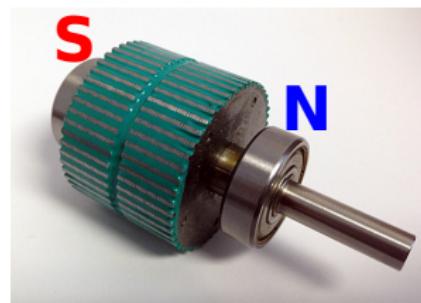

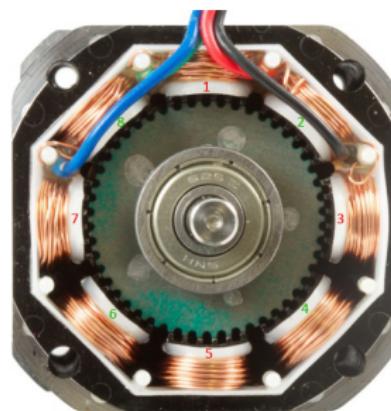

PERMANENT MAGNET STEPPER MOTOR FEATURES

- Stepping motors with magnetized rotors provide greater flux and torque than motors with variable reluctance
- Subjected to influence from the back-EMF of the rotor
- This limits the maximum speed

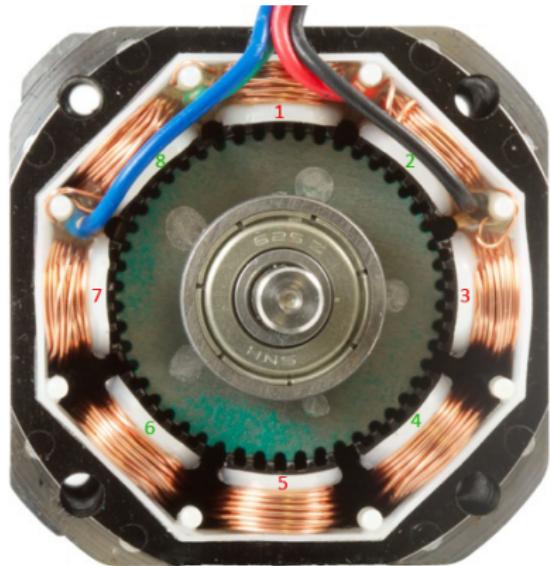

HYBRID STEPPER MOTORS

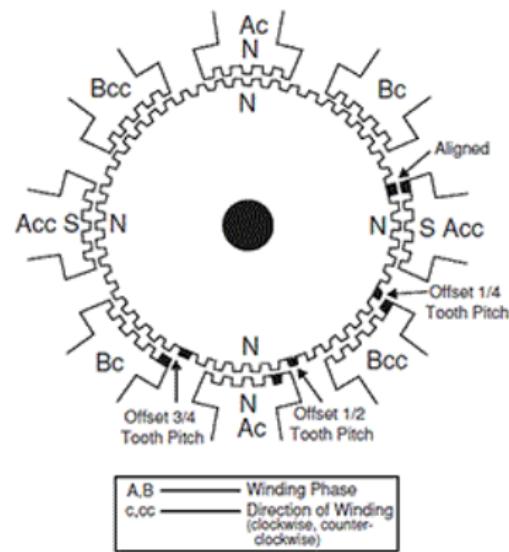

- combine a permanent magnet and a rotor with metal teeth to provide features of the variable reluctance and permanent magnet motors
- the rotor teeth provide a smaller magnetic circuit resistance in some rotor positions, which improves static and dynamic torque
- more expensive than other steppers, but they use smaller steps, have greater torque, and have greater maximum speeds
- most common type of stepper

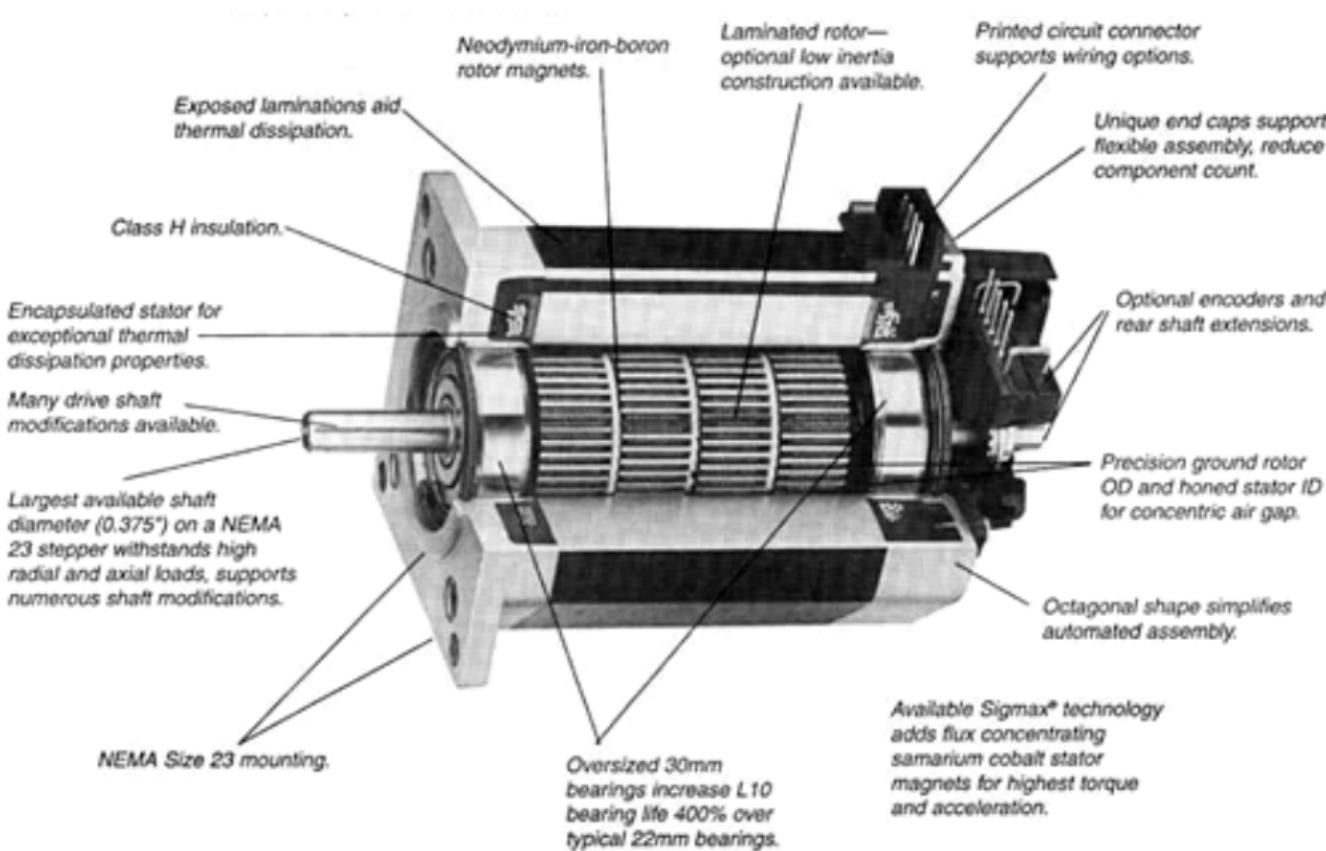

HYBRID STEPPING MOTOR OPERATION

Source: [MinebeaMitumi](http://MinebeaMitumi.com)

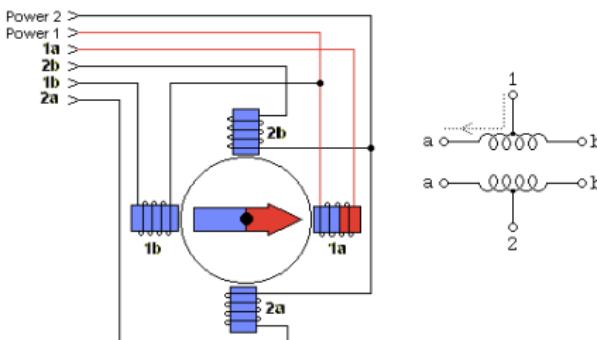

BIPOLAR MOTOR WINDINGS

- In a bipolar winding the current flow on the coils is reversed, which reverses electromagnetic polarity
- All the windings can be used to drive the motor
- Four wires
- No common center connection.
- Two independent sets of coils
- Need H-bridge to reverse direction of current in coils

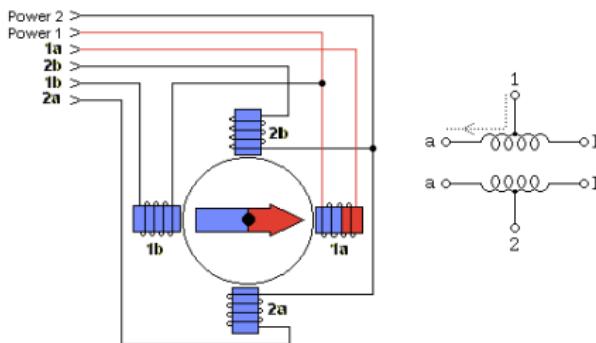

UNIPOLAR MOTOR WINDINGS

Unipolar stepping motor are made of two windings.

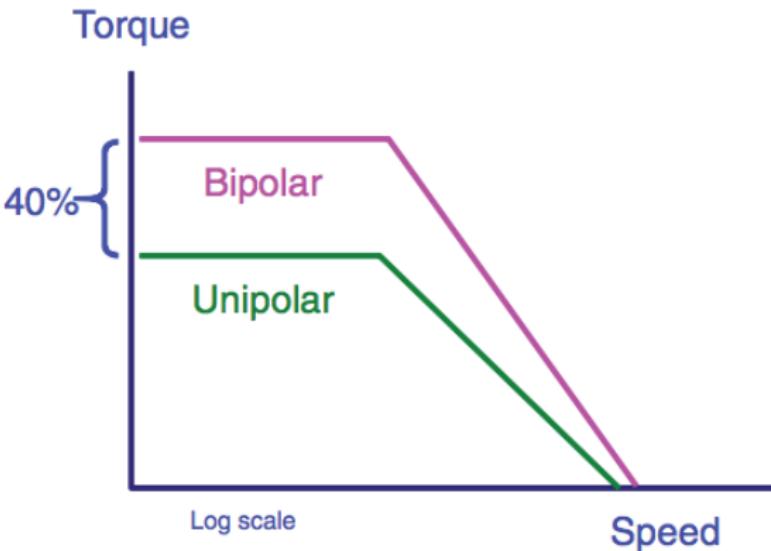

- Each windings has a center tap either brought outside motor separately or connected together and brought outside as one wire
- Therefore unipolar motors have 5 or 6 wires

UNIPOLAR MOTOR WINDINGS

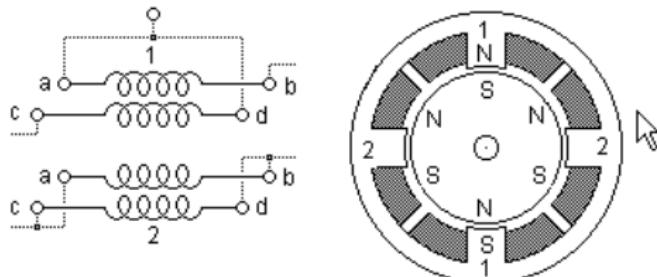

- Center taps normally tied to GND, ends of the coils alternately V+
- Unipolar drivers always energize the coils in the same direction.
- Current flow is never reversed, hence the name unipolar
- Less available torque because only half of the coils energized at a time

BIPOLAR DELIVERS MORE TORQUE THAN UNIPOLAR

- All of bipolar windings used each time
- Only half of unipolar winding used at once

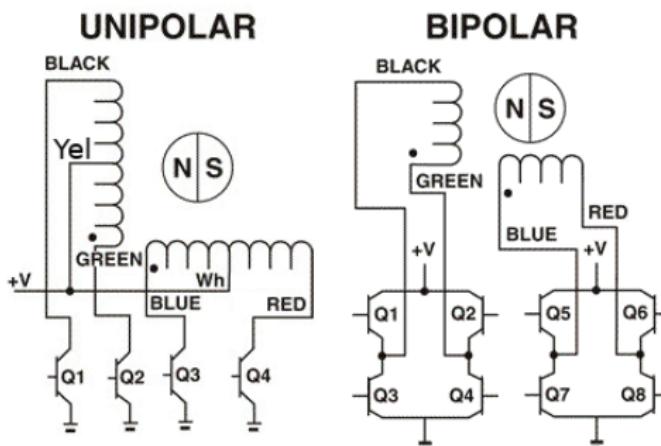

BIFILAR STEPPER MOTOR

- Almost identical to bipolar stepper motors
- But have two windings per phase in parallel
- Can be used as unipolar or bipolar motors
- In addition both parallel coils can be used in bipolar mode with half the normal drive supply voltage
- Thus this is a flexible design but at the cost of having extra wires

CONTROLLING A STEPPER MOTOR WITH AN ARDUINO

UNIPOLAR VERSUS BIPOLAR CIRCUITRY

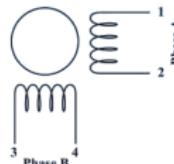

- Only need simple switching units to operate
- Don't need H-bridge
- Unipolar drivers can be implemented with simple transistor circuitry

- Bipolar drivers need H-bridge circuitry to reverse the current flow through the coil
- *Not really a problem these days!*

FULL-STEP CONTROL PROGRAM

```
#define DIR_A 12
#define PWM_A 3
#define DIR_B 13
#define PWM_B 11

const int delayMs = 100;

void setup() {
    pinMode(DIR_A, OUTPUT);
    pinMode(DIR_B, OUTPUT);

    pinMode(9, OUTPUT); digitalWrite(8, LOW); //No braking ch. A
    pinMode(8, OUTPUT); digitalWrite(8, LOW); //No braking ch. B
}
```

FULL-STEP CONTROL PROGRAM

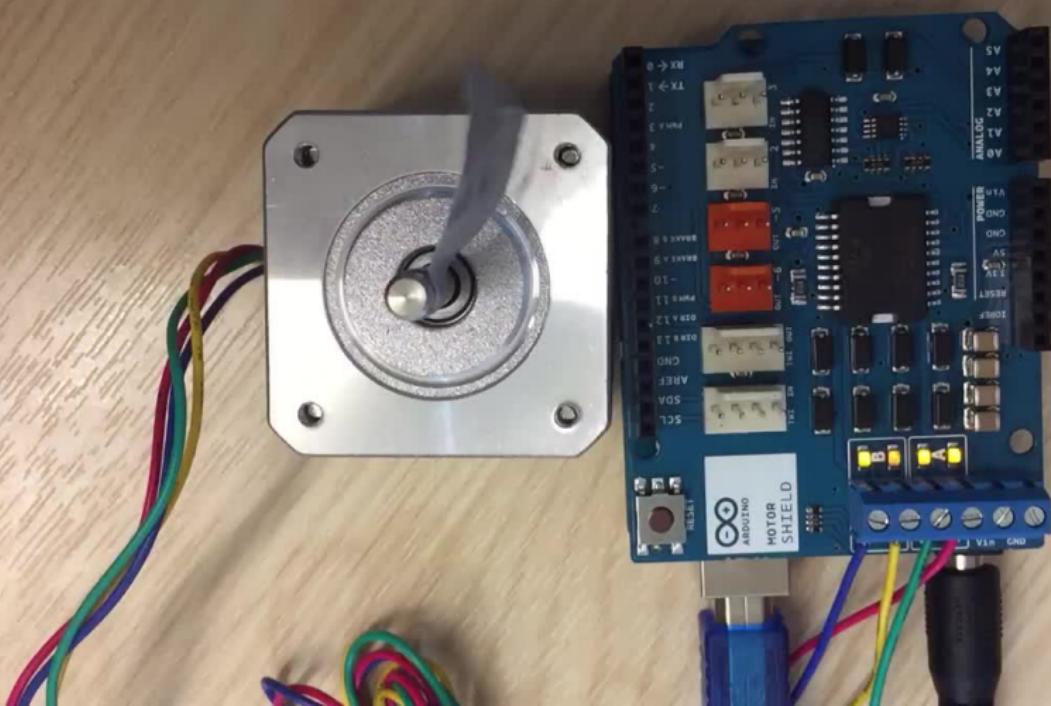

```
void loop(){

    digitalWrite(DIR_A, HIGH); // Ch. A forward
    digitalWrite(DIR_B, HIGH); // Ch. B forward
    analogWrite(PWM_A, 255); // Ch. A on
    analogWrite(PWM_B, 0); // Ch. B off
    delay(delayMs);

    analogWrite(PWM_A, 0); // Ch. A off
    analogWrite(PWM_B, 255); // Ch. B on
    delay(delayMs);

    digitalWrite(DIR_A, LOW); // Ch. A backwards
    digitalWrite(DIR_B, LOW); // Ch. B backwards
    analogWrite(PWM_A, 255); // Ch. A on
    analogWrite(PWM_B, 0); // Ch. B off
    delay(delayMs);

    analogWrite(PWM_A, 0); // Ch. A off
    analogWrite(PWM_B, 255); // Ch. B on
    delay(delayMs);
}
```

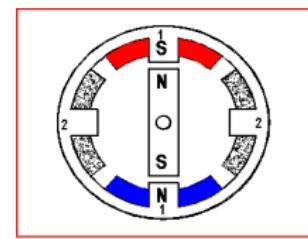

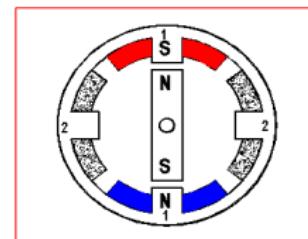

STEPPER MOTOR MODES

STEPPING MOTOR CONTROL MODES

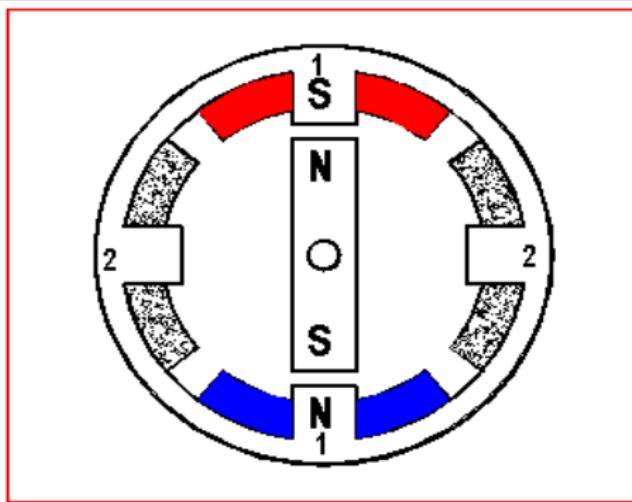

There are several stepper motor drive modes:

- Full-step mode
- Double-step mode
- Half-step mode
- Micro step Mode

Each of these modes controls stepping motor phases in different ways

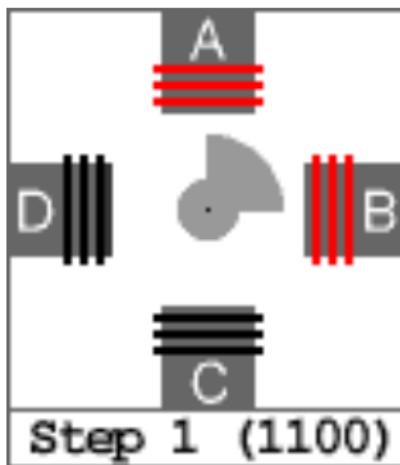

FULL STEP OPERATION

For this motor:

- 1 phase on at a time
- Four steps per revolution
- $360^\circ / 4 = 90^\circ$ rotation per step

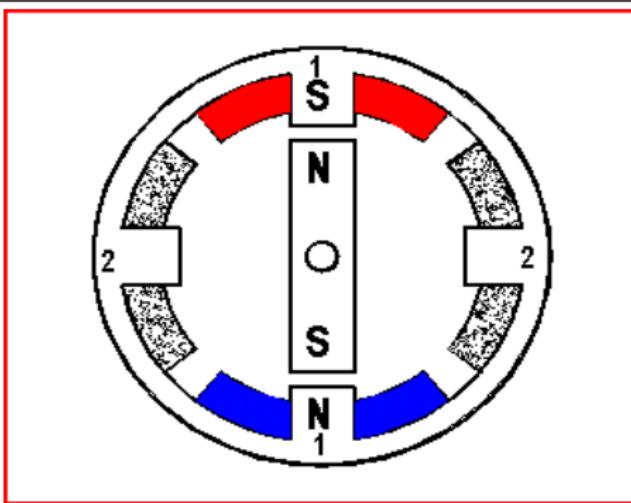

2 PHASES FULL STEP OPERATION

For this motor:

- 2 phases on at a time
- Four steps per revolution
- $360^\circ / 4 = 90^\circ$ rotation per step
- More output torque than 1 phase operation

HALF STEP OPERATION

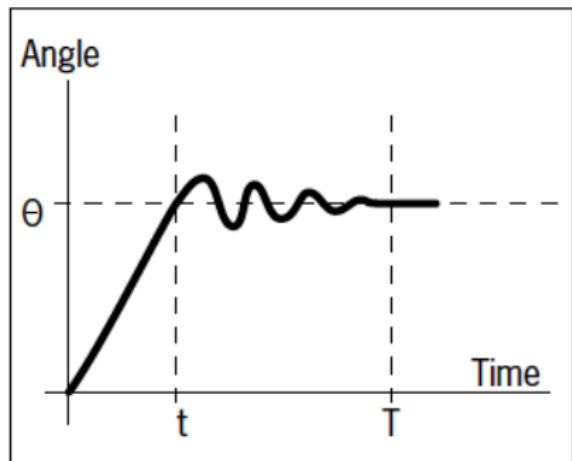

For this motor:

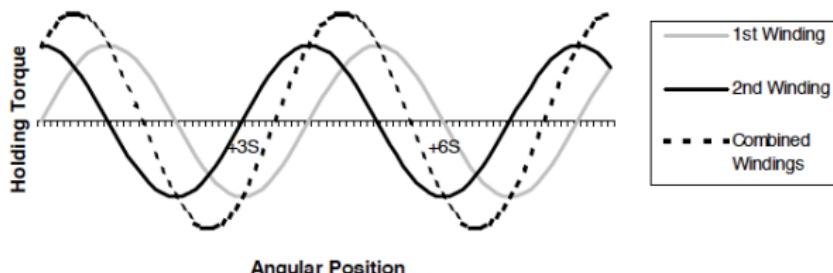

- 1 or 2 phases on at a time
- Eight steps per revolution
- $360^\circ / 8 = 45^\circ$ rotation per step

SINGLE STEP RESPONSE AND RESONANCES

- Single step operation may result in resonances
- Depends on moment of inertia of motor and also resorting force to step alignment equilibrium position
- Also load dependent
- It will be damped by frictional and viscous loads
- Half step and micro stepping helps to reduce these unwanted effects
- In any case pulsing at resonant frequency is inadvisable

MICROSTEPPING

- Single stepping a motor results in jerky movements of the motor, especially at lower speeds
- Sine-cosine micro stepping adjusts the current in each winding so the net torque is constant
- Gradually transfers current from one winding to another
- Normally achieved by pulse-width modulating the voltage across the windings of a motor
- The duty cycle of the signal of one winding is decreased as the duty cycle of the signal of other winding is increased

SINE-COSINE MICROSTEPPING

$$T_1 = H \sin(((\pi/2)/S)\theta)$$

where T_1 = torque of the first winding

$$T_2 = H \cos(((\pi/2)/S)\theta)$$

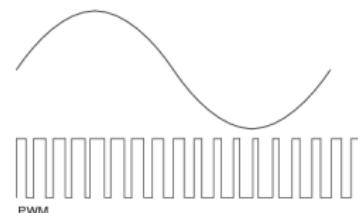

H = holding torque

S = step angle, in radians

$$I_1 = I_{MAX} \cos(((\pi/2)/S)\theta)$$

θ = shaft angle, in radians

$$I_2 = I_{MAX} \sin(((\pi/2)/S)\theta)$$

PWM

- In ideal motor torque produced by each winding proportional to the current and torques add linearly
- Saturation and fringe-field effects make real motors non-ideal
- In practice, close enough so can ignore nonlinearities

ARDUINO MICROSTEPPING EXAMPLE CODE

```
// demonstrate principle of microstepping
int microsteps = 200;      // microsteps for step
float amp = 255;          // scaling for output
int pulseDelay = 10;       // microseconds between write
int a[200];                // declare arrays
int b[200];
int idxG;

void setup() {
    int idx;

    Serial.begin(9600);    // initialize the serial port:
    idxG=0;                // init output index

    // build sin and cos array
    for (idx = 0 ; idx < microsteps; idx++) {
        a[idx] = amp * sin(idx * 2 * PI / microsteps);
        b[idx] = amp * cos(idx * 2 * PI / microsteps);
    }

    // set pin function
    pinMode(12, OUTPUT);
    pinMode(13, OUTPUT);
    pinMode(9, OUTPUT);
    pinMode(8, OUTPUT);

    // take breaks off
    digitalWrite(8, LOW);
    digitalWrite(9, LOW);
}
```

Define and initialize variables

Setup output index

Build sin and cos tables

Set digital pins use with motor shield to outputs

Take off the breaks

ARDUINO MICROSTEPPING EXAMPLE CODE

```

// write to specified stepper channel
void WriteValue(int value, int chanAnalog, int chanDigit)
{
    int valueAbs = abs(value);      // get absolute value
    analogWrite(chanAnalog, value); // write absolute value as PWM
    if (value > 0) {              // set direction +ve
        digitalWrite(chanDigit, HIGH);
    }
    else {                        // set direction -ve
        digitalWrite(chanDigit, LOW);
    }
}

void loop() {
    // debugging
    //   Serial.print(a);
    //   // separator for plot
    //   Serial.print(",");
    //   Serial.println(b);

    WriteValue(a[idxG], 3, 12); // write out chan A sin value
    WriteValue(b[idxG], 11, 13); // write out chan B cos value

    idxG++; // update index
    if (idxG == microsteps) {
        idxG = 0;
    }
    delayMicroseconds(pulseDelay); // wait delay
}

```

Can only write 0-255 to PWM output
So take absolute value

Use sign of value to set output direction

For debugging

Write out sin and cos
values to stepper

Update index

Delay

CHARACTERISATION OF STEPPER MOTORS

STEPPER MOTOR STEP PARAMETERS

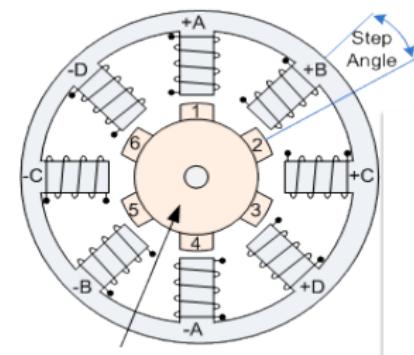

Step angle is given by: $\alpha = \frac{360}{n_s}$ where n_s is the number of steps for the stepper motor (integer)

Total angle through which the motor rotates (A_m) is given by:

$$A_m = n_p \alpha \quad \text{where } n_p = \text{number of pulses received by the motor.}$$

Angular velocity is given by: $\omega = \frac{2\pi f_p}{n_s}$ where f_p = pulse frequency

Speed of rotation is given by: $N = \frac{60 f_p}{n_s}$

EXAMPLE: STEP PARAMETERS

A stepper motor has a step angle = 3.6°.

How many steps are there per revolution?

$$3.6^\circ = 360^\circ / n_s;$$

$$n_s = 360^\circ / 3.6^\circ = 100 \text{ steps per rev}$$

How many pulses are required for the motor to rotate through 10 complete revolutions?

For 10 complete revolutions:

$$10 * (360^\circ) = 3600^\circ = A_m$$

$$\text{Therefore } n_p = 3600 / 3.6 = 1000 \text{ pulses}$$

What pulse frequency is required for the motor to rotate at a speed of 100 rev/min?

$N = 100 \text{ rev/min}$: requires 100x100 pulses in 60s

$$10000 = 60 f_p$$

$$f_p = 10,000 / 60 = 166.667 = 167 \text{ Hz}$$

CURRENT FLOW IN STEPPER MOTORS

Summing voltages around circuit

$$v_s = v_R + v_L$$

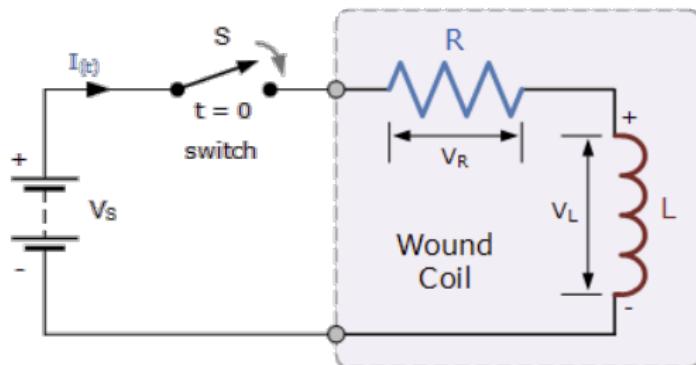

Voltage across resistor

$$v_R = IR$$

Voltage across induction

$$v_L = L \frac{dI}{dt}$$

$$\Rightarrow v_s = IR + L \frac{dI}{dt}$$

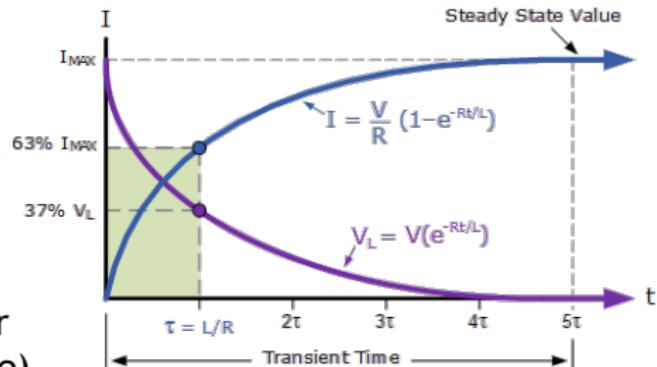

Current response to switch on given by

$$I = \frac{V_s}{R} \left(1 - e^{\frac{-Rt}{L}} \right)$$

CURRENT FLOW IN STEPPER MOTORS

$$I = \frac{V_s}{R} \left(1 - e^{\frac{-Rt}{L}} \right)$$

- $\tau = L/R$ is the time constant for the LR circuit in seconds
- When time $t = \tau = L/R$ (i.e. after a time constant's worth of time) the L and the R terms cancel

$$I = \frac{V_s}{R} \left(1 - e^{-1} \right) = \frac{V_s}{R} \left(1 - 0.3679 \right) = 0.6321 \frac{V_s}{R}$$

- After switch on current reaches 63% of maximum value after τ seconds
- Maximum current value given by $I_{MAX} = \frac{V_s}{R}$

CURRENT FLOW IN STEPPER MOTORS

- So like DC motors current flowing through coils depends on inductance
- Differentiating the expression for current I

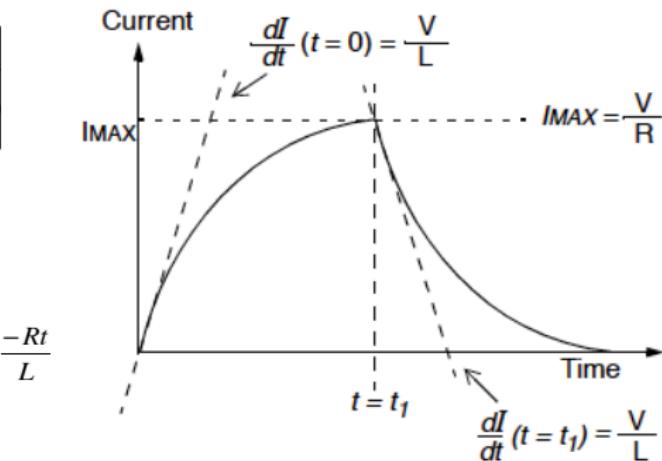

$$\Rightarrow \frac{dI}{dt} = \frac{dI}{dt} \left[\frac{V_s}{R} \left(1 - e^{\frac{-Rt}{L}} \right) \right]$$

Now since $\frac{d}{dt}(e^u) = \frac{du}{dt} e^u$

$$\frac{dI}{dt} = \frac{V_s}{R} \frac{-R}{L} - e^{\frac{-Rt}{L}} = \frac{V_s}{L} e^{\frac{-Rt}{L}}$$

- When time t is zero

$$\frac{dI}{dt} = \frac{V_s}{L} e^{\frac{-R \cdot 0}{L}} = \frac{V_s}{L}$$

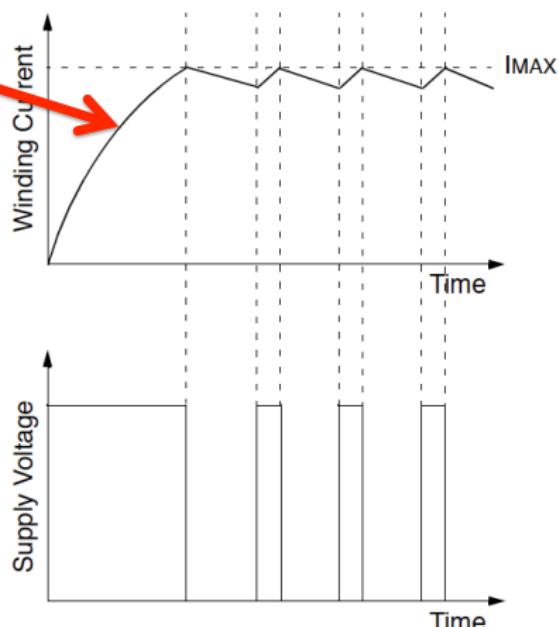

- Which just depends on voltage V_s , inductance L and **NOT** resistance R

CHOPPER CONTROL OF CURRENT

- To achieve good high rotational speed performance we want current applied to rise very fast!
- This requires high supply voltage
- But then

$$I_{MAX} = \frac{V_s}{R}$$

- may then exceed the motor spec
- Also R low for high performance units
- Solution is to measure current and use PWM to regulate it by modulate supply to coils to prevent current exceeding stepper ratings
- This is now implemented in commercially available stepper motor drivers like the A4988

ROUGH CALCULATION OF MAX PULSE RATE

- When time t is zero $\frac{dI}{dt} = \frac{V_s}{L}$
- Therefore if we drive with a high voltage using a current limiting controller, current will initially rise linearly and

$$\frac{dI}{dt} \approx \frac{\Delta I}{\Delta T} \Rightarrow \frac{\Delta I}{\Delta T} \approx \frac{V_s}{L} \Rightarrow \Delta I \approx \frac{V_s}{L} \Delta T$$

- Therefore starting from $I=0$ and going to maximum rating current for stepper I_{smax} will take T_{rise} seconds, where

$$I_{smax} \approx \frac{V_s}{L} T_{rise} \Rightarrow T_{rise} = I_{smax} \frac{L}{V_s}$$

- For a pulse current must go up by then down again

$$\Rightarrow T_{pulse} = 2 I_{smax} \frac{L}{V_s}$$

ROUGH CALCULATION OF MAX PULSE RATE

From

$$T_{pulse} = 2 I_{smax} \frac{L}{V_s} \quad \text{since} \quad f_{pulse} = \frac{1}{T_{pulse}}$$

$$\Rightarrow f_{pulse} = \frac{V_s}{2 I_{smax} L}$$

$$\Rightarrow RPM_{max} = \frac{V_s}{2 I_{smax} L} \cdot \frac{60}{N_s} \quad \begin{array}{l} \bullet \text{ Where } N_s \text{ is pulses per revolution} \\ \text{for the stepper} \end{array}$$

Typical stepper motor example:

- $L=3\text{mH}$ and $V_s=12\text{v}$
- $N_s=200$ pulses per rev, $I_{smax}=1\text{A}$

$$\Rightarrow RPM_{max} = \frac{12}{2 \times 1 \times 3/1000} \cdot \frac{60}{200} = 600$$

NB: this assumes
current rises linearly
Only true if V_s large and
 $I_{smax} \ll V_s/R$

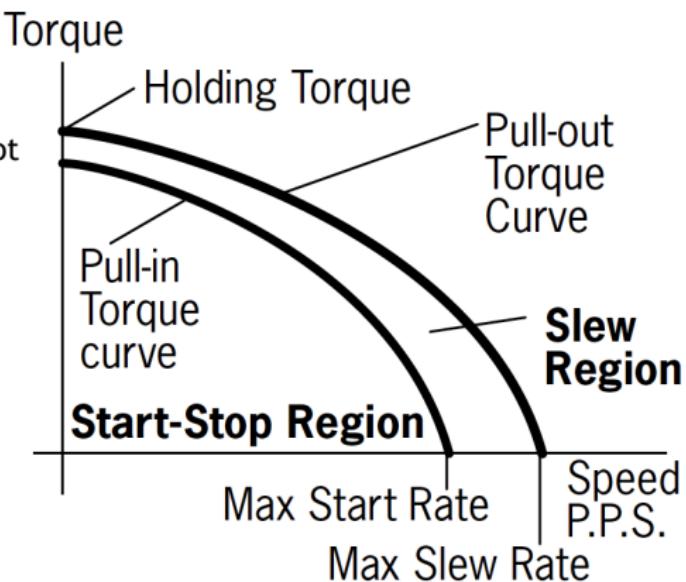

STEPPER MOTOR TORQUE-SPEED CHARACTERISTIC

Detent torque

- Amount of torque the motor produces when the windings are not energized
- This resists the shaft turning

Holding torque

- Amount of torque needed in order to move the motor one full step when the windings are energized but the rotor is stationary

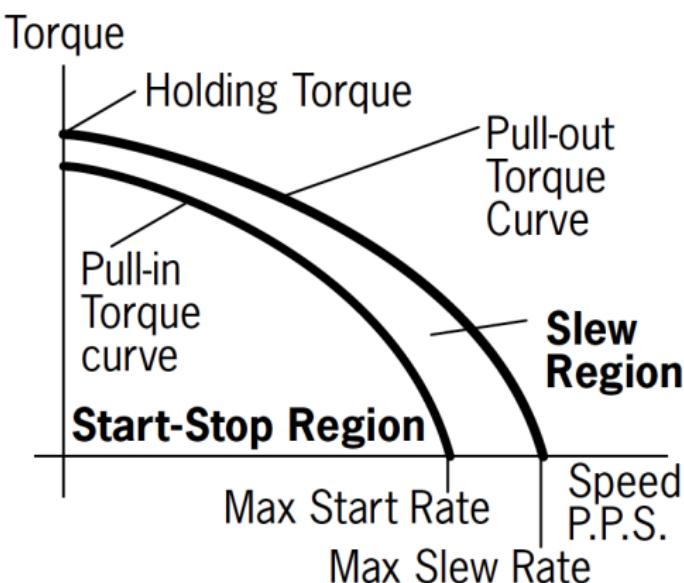

STEPPER MOTOR TORQUE-SPEED CHARACTERISTIC

Pull-in Torque Curve

- Maximum torque at given speeds that the motor can start, stop or reverse in synchrony with input pulses.
- Motor cannot start at a speed beyond this curve
- Motor cannot instantly reverse or stop with any accuracy at a point beyond this curve

Stop / Start Region

- Area underneath pull-in curve.
- Within this region motor can start, stop, or reverse “instantly”

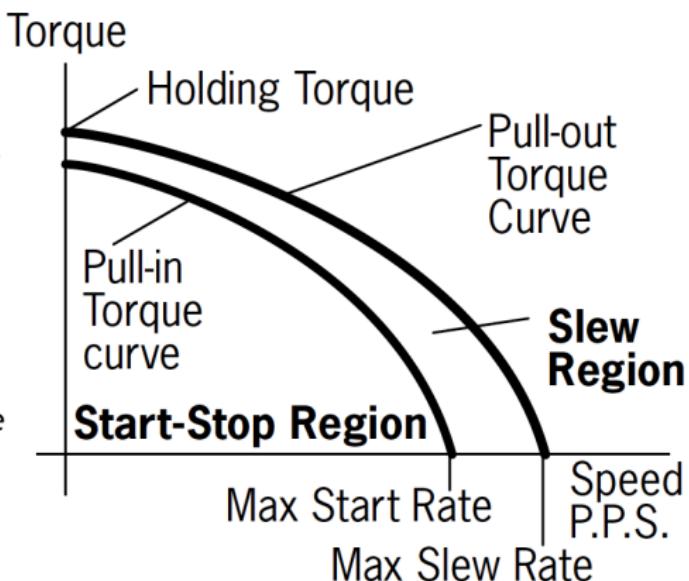

STEPPER MOTOR TORQUE-SPEED CHARACTERISTIC

Pull-out Torque Curve

- Maximum torque at given speeds that the motor can generate while running synchronously
- Above this curve motor will stall

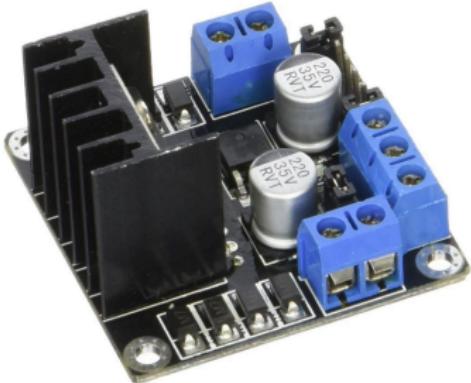

Slew Range

- Area between the pull-in and the pull-out curves
- In this region motor speed must be adjusted gradually to maintain synchronism

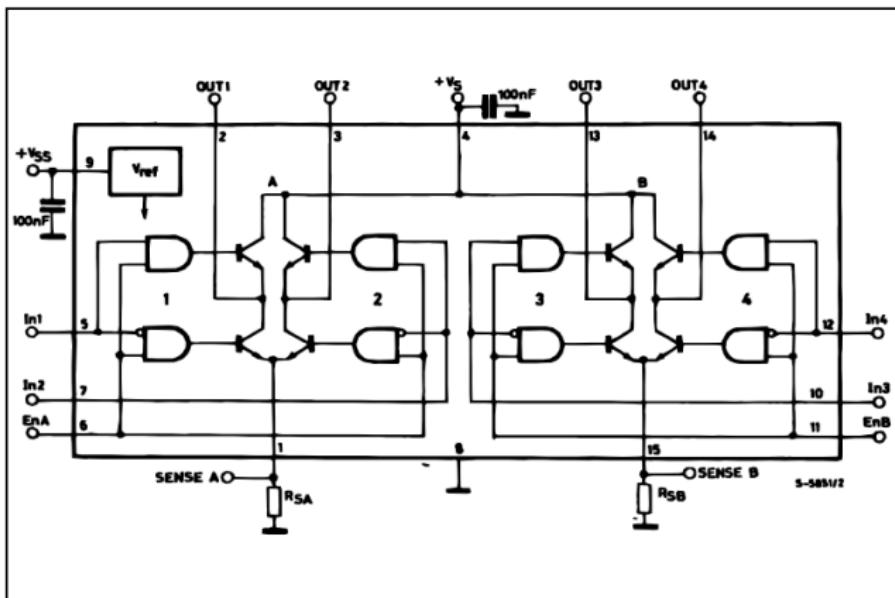

STEPPER MOTOR DRIVERS

L298N DC STEPPER MOTOR CONTROLLER

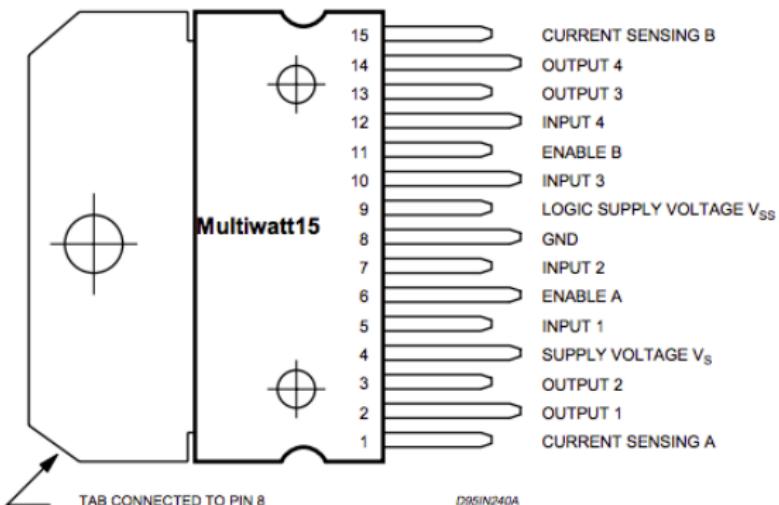

- L298N as main driver chip makes strong driving ability/small heating/strong anti-interference/low calorific value
- Use large-capacity filter capacitors and diode with freewheeling protection function, increasing reliability
- Dual-channel H-bridge driver working mode creates higher working efficiency
- To avoid damage the voltage stabilizing chip, please use an external 5V logic supply when using more than 12V driving voltage
- With large capacitance filter capacitor and after flow protection diode, more stable and reliable

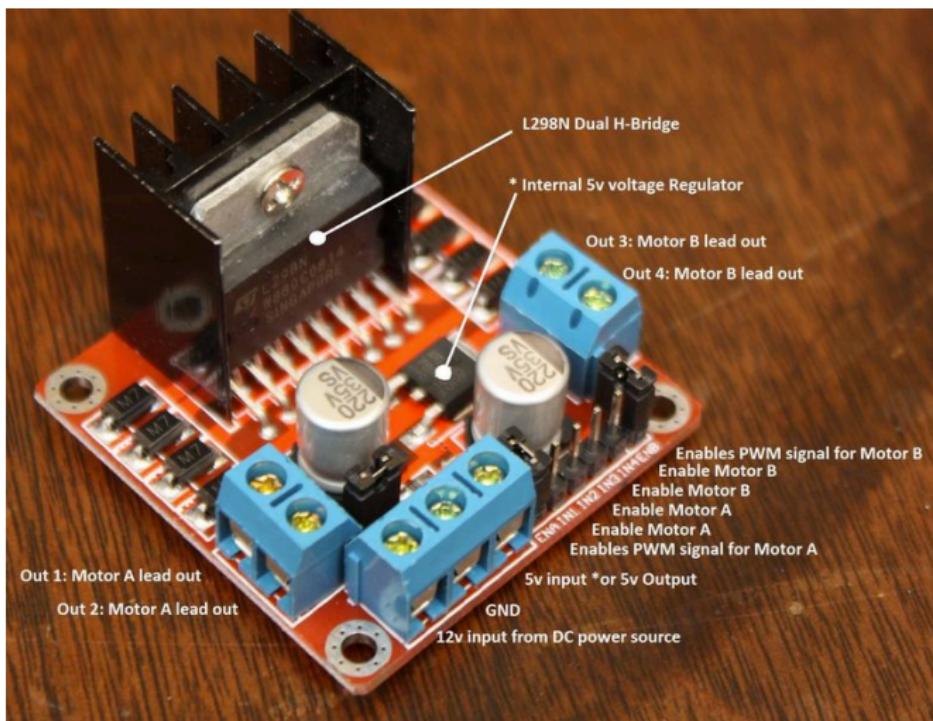

L298N DC STEPPER MOTOR CONTROLLER

ON THE ARDUINO MOTOR SHIELD

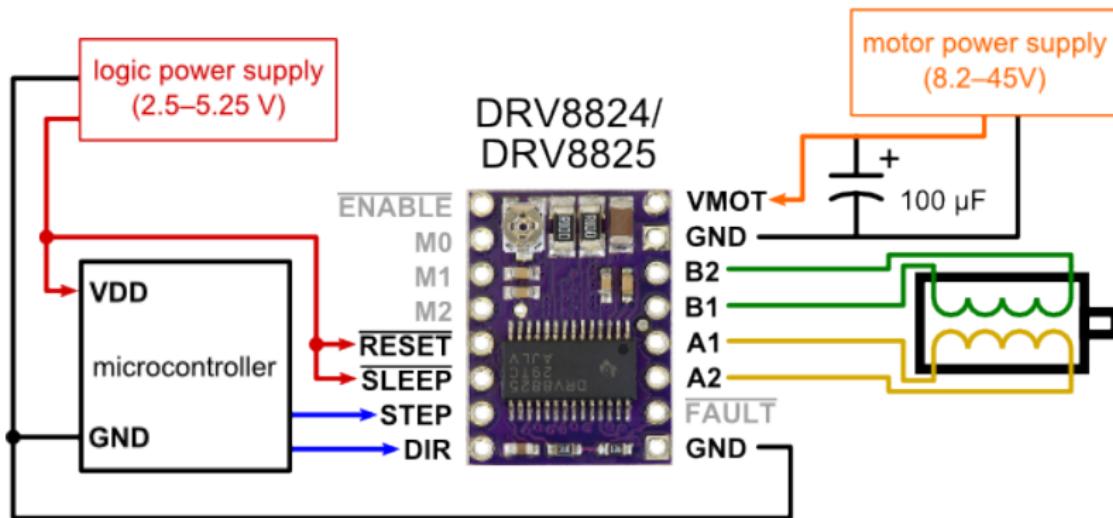

DRV8825 STEPPER MOTOR CONTROLLER

- Simple step and direction control interface
- Six different step resolutions: full-step, half-step, 1/4-step, 1/8-step, 1/16-step, and 1/32-step
- Adjustable current control lets you set the maximum current output with a potentiometer, which lets you use voltages above your stepper motor's rated voltage to achieve higher step rates
- Intelligent chopping control that automatically selects the correct current decay mode (fast decay or slow decay)
- 45 V maximum supply voltage
- Built-in regulator (no external logic voltage supply needed)
- Can interface directly with 3.3 V and 5 V systems
- Over-temperature thermal shutdown, over-current shutdown, and under-voltage lockout
- Short-to-ground and shorted-load protection

DRV8825 STEPPER MOTOR CONTROLLER

STRENGTHS AND WEAKNESSES

ADVANTAGES AND DISADVANTAGES OF STEPPERS

Advantages

- Cheap and robust way to directly generate relatively high torque at low speeds so can drive many loads without gearing
- Long life with only bearing to wear out (no brushes)
- Stepper motor can be controlled without feedback
- Excellent positional repeatability
- Open loop - motors response to digital input pulses
- Brushless - no contact brushes to wear out
- Incremental steps - rotation angle proportional to the input pulse
- Standard NEMA frame sizes facilitates mounting and replacement of motors
- Failsafe – since just stops working and doesn't go berserk if fails (e.g. unlike a servo motor if it loses its encoder signal)

ADVANTAGES AND DISADVANTAGES OF STEPPERS

Disadvantages

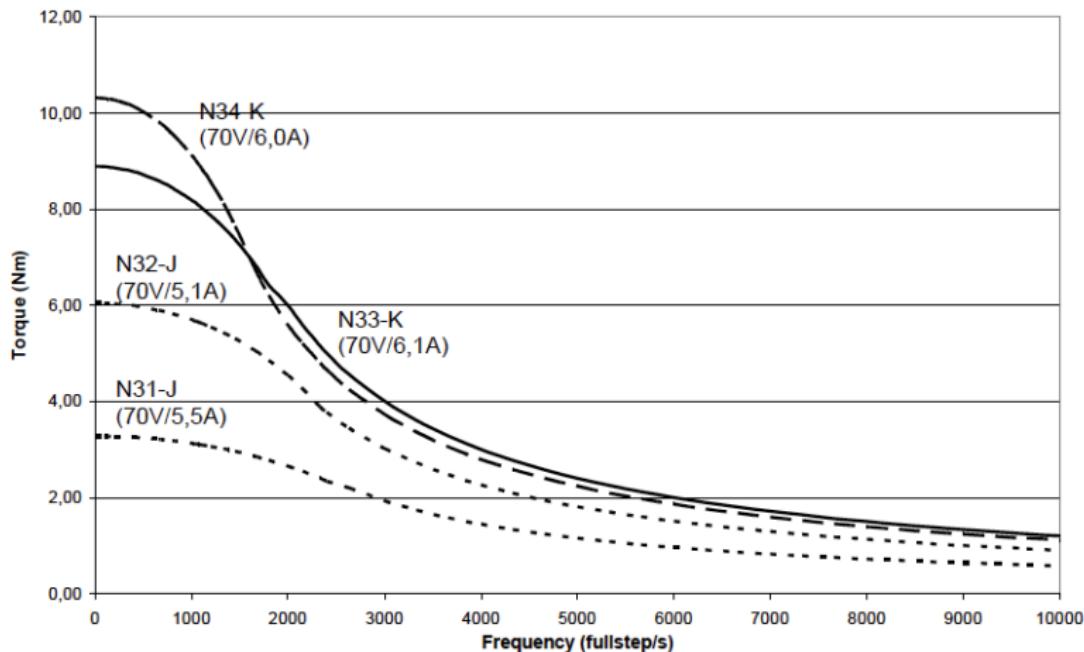

- Low efficiency since the motor draws substantial power regardless of load and must do so to hold a static position (otherwise it will lose position synchronization)
- Torque can fall off rapidly as speed increases
- Resonance can occur if not properly controlled and requires micro-stepping to ensure smooth movement. (last 2 issues now less of a problem using the latest switching current limiting controllers)
- Synchronization will be lost if momentarily overloaded since lost steps cannot be noticed since there is no feedback
- Motors exhibit a low torque to intrinsic inertia ratio so have a high rotational time constant (i.e. cannot generate large angular accelerations)
- Stepper motor normally run very hot in high performance configurations (much too hot to touch)
- Not easy to operate at very high speeds (i.e. > 2000rpm)
- Motor normally generates a lot of acoustic noise at moderate to high speeds
- Low output power for size and weight (i.e. motors are heavy for output power they produce)

STEPPER MOTOR DESIGN ISSUES

- Above Curie temperature a permanent magnet will lose its magnetics.
- Needs to be higher than the operating temperature of the stepper motor it will no longer generate torque.
- Even before the Curie temperature the magnetic flux density will reduce
- As the speed of rotation of a stepper motor increases, permanent magnet steppers will induce a back EMF in the windings
- This will oppose the flow of current, and at high speeds it may drop significantly and thereby reduce available torque output
- Therefore higher supply voltages are needed to run at high rotational speeds
- Since simple H-bridge drive circuits limit current in the steppers using the resistance of the windings, this places a limit of the maximum applied voltage that can be used with such drive circuits
- The issues of back EMF induced by stepper rotation can be much more elegantly dealt using constant current stepper drives that regulate the current

TYPICAL STEPPER TORQUE CHARACTERISTICS

Size N3 (selected windings, at 70V)

APPLICATIONS

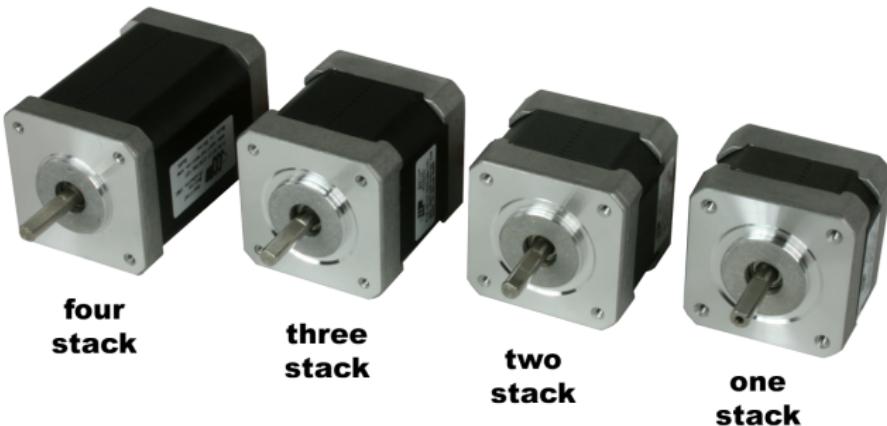

WIDE RANGE OF STANDARD NEMA FRAMES

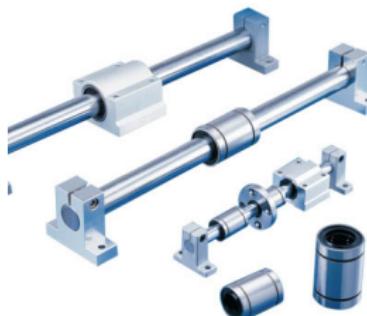

www.pololu.com

- NEMA stepper units have standard frames sized
- This facilitates exchanging units and upgrading

VARIABLE NUMBER OF STACKS

CNC MILL USING STEPPERS

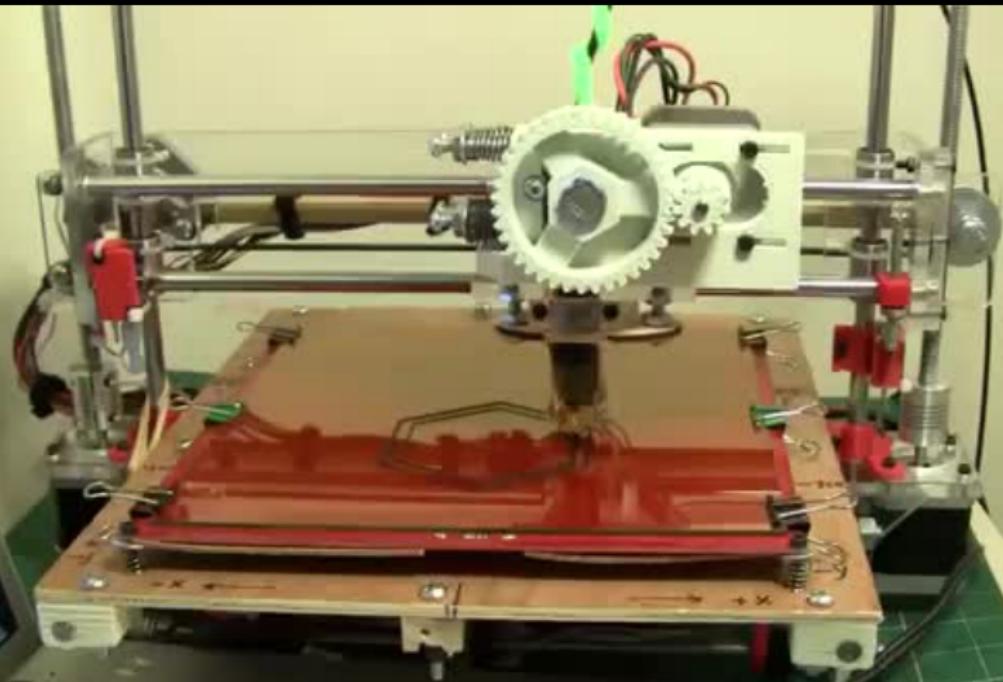

- Using linear bearing to implement low friction high precision tool movement

- Using a stepper to directly drive a ball screw on each axis to generate linear movement

- Here simple CNC using ZYX control of a router to cut material
- Larger machines move the table and not the cutter mechanism

SERVO MOTOR VERSUS STEPPER MOTOR

- Fast and responsive 100K RPM+
- No lost counts
- Smaller increments of motion
- Lower pole count
- Better efficiencies / linearity's
- High acceleration rates possible
- **Expensive**

- Comparatively cheap
- Very reliable and limited by bearing life
- Good torque at low
- **Lots of current handling to operate micro stepping modes - lots of heat => inefficient**
- Can get resonance effects
- Large size
- Can be quite heavy
- Don't work at high speeds > 2000rpm

GEARED STEPPER MOTOR

- Stepper motors can also be sourced with gearboxes attached
- Provides extra torque and reduces granularity in output

Technique parameter

Item	Specifications
Step Angle Accuracy	$\pm 5\%$ (full step, no load)
Resistance Accuracy	$\pm 10\%$
Inductance Accuracy	$\pm 20\%$
Temperature Rise	80°CMax.(ratod current, 2 phase on)
Ambient Temperature	-10°C~+50°C
Insulation Class	B
Dielectric Strength	500VAC for one minute
Shaft Radial Play	0.06Max.(450 g-load)
Shaft Axial Play	0.08Max.(450 g-load)
